Data for: Improved accuracy in OCT diagnosis of rare retinal disease using few-shot learning with generative adversarial networks

Published: 29 October 2020 | Version 2 | DOI: 10.17632/btv6yrdbmv.2
Contributor: TaeKeun Yoo

Description

The retinal OCT images of rare diseases were extracted by using the Google image and Google dataset search that included English keywords including central serous chorioretinopathy (CSC), macular telangiectasia (MacTel), macular hole (MH), Stargardt disease, retinitis pigmentosa (RP). These rare diseases were selected according to a previous review article about OCT diagnosis. The images possessing rare diseases were manually classified by two board-certified ophthalmologists, and ambiguous images were removed to clarify the image domains.

Additional file "Segmentation_manual.zip" offers manually segmented OCT images for pathologic lesions.
